Program Element III. Research on earthquake occurrence, physics and effects  
Key Words: Age Dating; Tectonic Geomorphology; Quaternary Fault Behavior

**Investigations Undertaken**

This project is designed to provide a reliable slip rate estimate for the Sierra Madre-Cucamonga (SMC) fault system that bounds the southern margin of the San Gabriel Mountains (Figure 1). We proposed to (1) produce digital elevation models using the early 1920's USGS 6 minute topographic map series (5 foot contour intervals), (2) produce detailed maps of fault scarps and Quaternary geomorphic surfaces, (3) determine the age of these surfaces using cosmogenic surface exposure age dating techniques, and (4) calculate uplift rates and slip rates across the SMC fault system in the San Fernando and San Gabriel Valleys. Our study included the following specific tasks:

Task 1: Expand earlier tectonic geomorphic analysis and mapping.

Task 2: Sample collection

Task 3: Cosmogenic dating

Task 4: Determine minimum uplift and dip-slip rates across the fault zone

During the past year, we have completed the first round of sampling and cosmogenic dating of surface samples collected from the abandoned geomorphic surfaces along the 1971 San Fernando surface rupture (Figure 2) and along the Cucamonga fault (Figure 4). CWU graduate student, Jake Horner, processed and analyzed Be and Al isotopes at the Center for Accelerator Mass Spectrometry at LLNL from samples collected from alluvial surfaces in the Pacoima Wash area. These samples help constrain fault slip rates along the San Fernando segment of the Sierra Madre fault system. Three quartz-rich cobbles from the active Pacoima Wash yield modern <sup>10</sup>Be and <sup>26</sup>Al ages, which indicate zero inheritance from the source area. Preliminary analyses of using <sup>10</sup>Be and <sup>26</sup>Al surface dating methods on alluvial cobbles from the Qt4 Pacoima Wash surface of Lindvall et al. (1995) yield surface exposure ages of 33,240 ±1564 yrs, 31,195 ±1287,

and  $31,024 \pm 1073$  (Figure 2). This gives a mean surface exposure age  $31,820 \pm 2292$  years. The minimum vertical separation across Qt4 surface includes the 1971 surface rupture and two older scarps that offset Qt2-Qt5 is  $27 \text{ m} \pm 1 \text{ m}$ .

This gives a minimum vertical uplift rate of  $0.85 \pm 0.08$  mm/yr. Additional sampling by the PI's and Jake Horner (graduate student) will provide additional age control to the Qt4 surface, as well as, other alluvial surfaces near crystalline range front faults.

We have also sampled, processed, and analyzed cobbles from the Day Canyon fan, which is offset by the Cucamonga fault. Preliminary analyses using  $^{10}\text{Be}$  and  $^{26}\text{Al}$  surface dating methods on alluvial cobbles from the Qyf1 surface (West Fan of Morton and Matti, 1987) yielded ages of  $39,738 \pm 1054$ ,  $35,230 \pm 1162$ ,  $33,183 \pm 1168$ ,  $41,331 \pm 1082$ , and  $40,910 \pm 1218$  years. These five samples yield a mean surface exposure age of  $38,078 \pm 2,291$  mm/yr. To the east, seven quart-rich cobbles from the Qyf1 surface (East Fan of Morton and Matti, 1987) yield cosmogenic surface ages of  $27,233 \pm 883$ ,  $26,411 \pm 906$ ,  $28,578 \pm 958$ ,  $23,458 \pm 956$ ,  $22,110 \pm 760$ , and  $26,242 \pm 1069$  years and yields a mean surface exposure age of  $25,672 \pm 2,270$  mm/yr.

The surface ages for the Qyf1 surface are substantially older than the  $\sim 13$  ka estimate of Morton and Matti (1987). Additional sampling and cosmogenic dating of quart-rich cobbles from the two Qyf1 surfaces will be performed. We will also complete a detailed topographic survey across the Qyf1 offset surfaces.

During the past year, we began to produce digital elevation models (DEMs) using the early 1920's USGS 6-minute topographic map series (5 foot contour intervals). INTEC Americas Corporation is presently producing 400 dpi 8-bit cropped geo-referenced scans of the following USGS 6-minute topographic maps, (1) 1927 Pacomia (surveyed 1924-1925), (2) 1939 Little Tujunga (surveyed 1933-1934), (3) 1942 Sunland (surveyed 1924-1925 and 1933), and (4) 1935 Sylmar (surveyed in 1925 and 1929). We will transfer our detailed maps of fault scarps and Quaternary geomorphic surfaces from the Pacomia area to these 5 m DEMs.

### **Non-technical summary**

This project is designed to determine slip rates across the Sierra Madre fault system, a key element in forecasting future seismic activity and accurately mapping seismic hazards. These data will help us to better understand how strain is accumulated and released on reverse faults in the greater metropolitan Los Angeles region.

### **Reports Published**

None.
